

QUALITY PARTS

CLUTCH MASTER CYLINDER AND SLAVE CYLINDER

Provide quality products and trustworthy services to
global auto parts consumers

COMPANY PROFILE

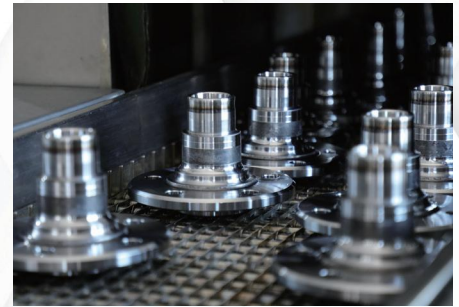

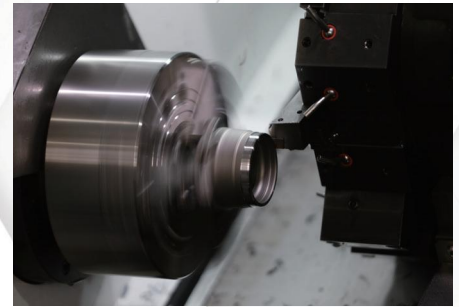

Hangzhou DUHUI Auto Parts Co., Ltd. was established in 2003 and is located in Xiaoshan District-Economic Development Zone, Hangzhou City. The company integrates supply chain development, quality management, warehousing, business operations, and other management capabilities, and is built through an information system to provide customers with one-stop services product solutions.

DUHUI has been focusing on automotive bearings for 20+ years, it mainly produces wheel hub, wheel bearing, release bearing, clutch master cylinder and slave cylinder, etc., covering more than 4,000+ auto parts models, including all mainstream models on the market.

PRODUCTION PROCESS

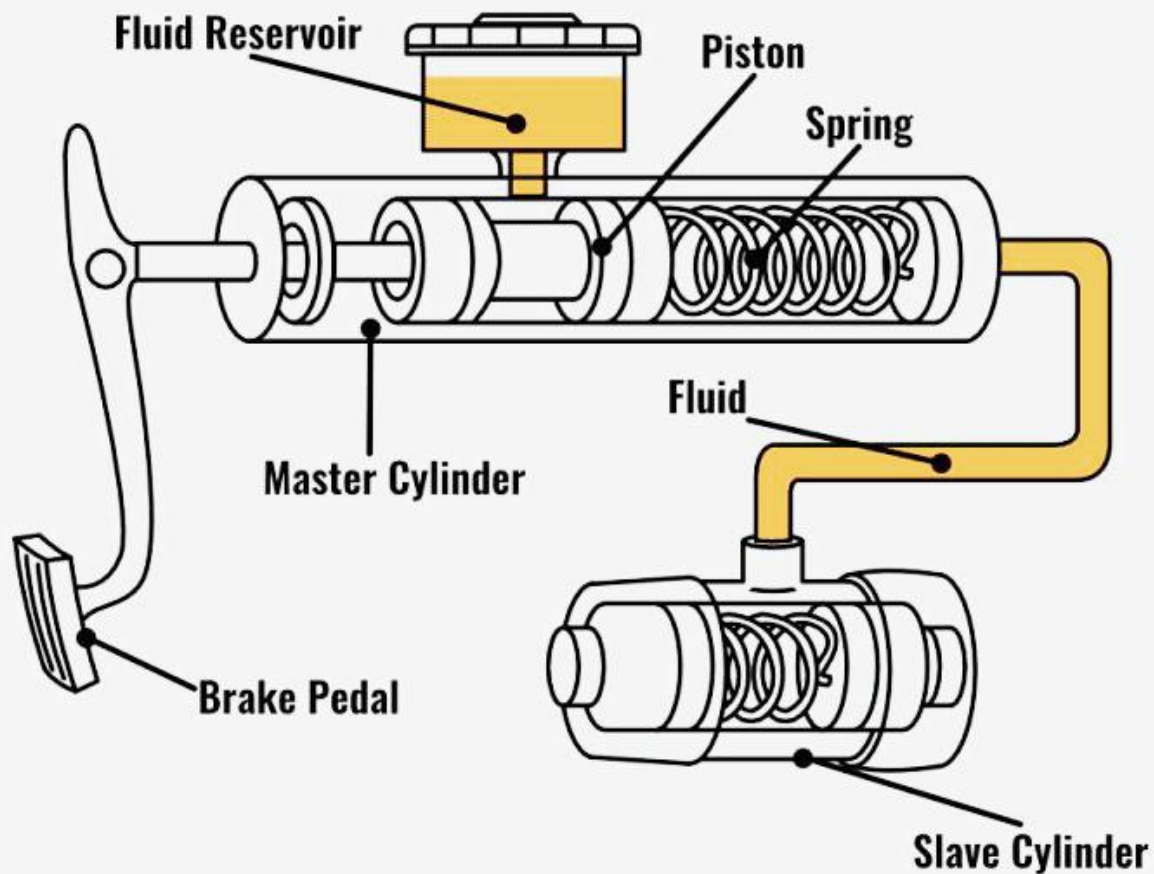

Duhui is equipped with a professional technical team. We constantly improving production processes and formulating strict process standards while dealing with technical problems, our excellent product quality stems from strict control of process standards.

QUALITY CONTROL

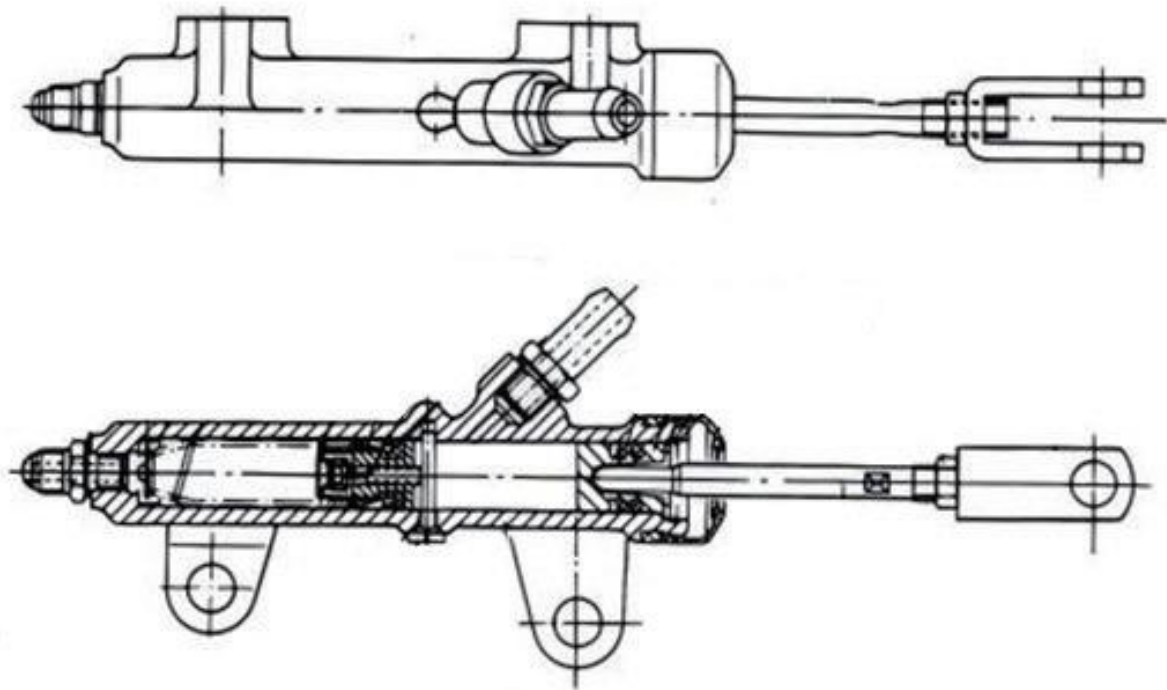

We installed a complete international-advanced testing and examining equipments to ensure the quality of our products. Our Quality Department strictly test each unit according to ISO/TS standards.

The Clutch Master Cylinder and Slave Cylinder are connected through a hydraulic or air pressure system (specifically depending on the vehicle design) to jointly control the operation of the clutch.

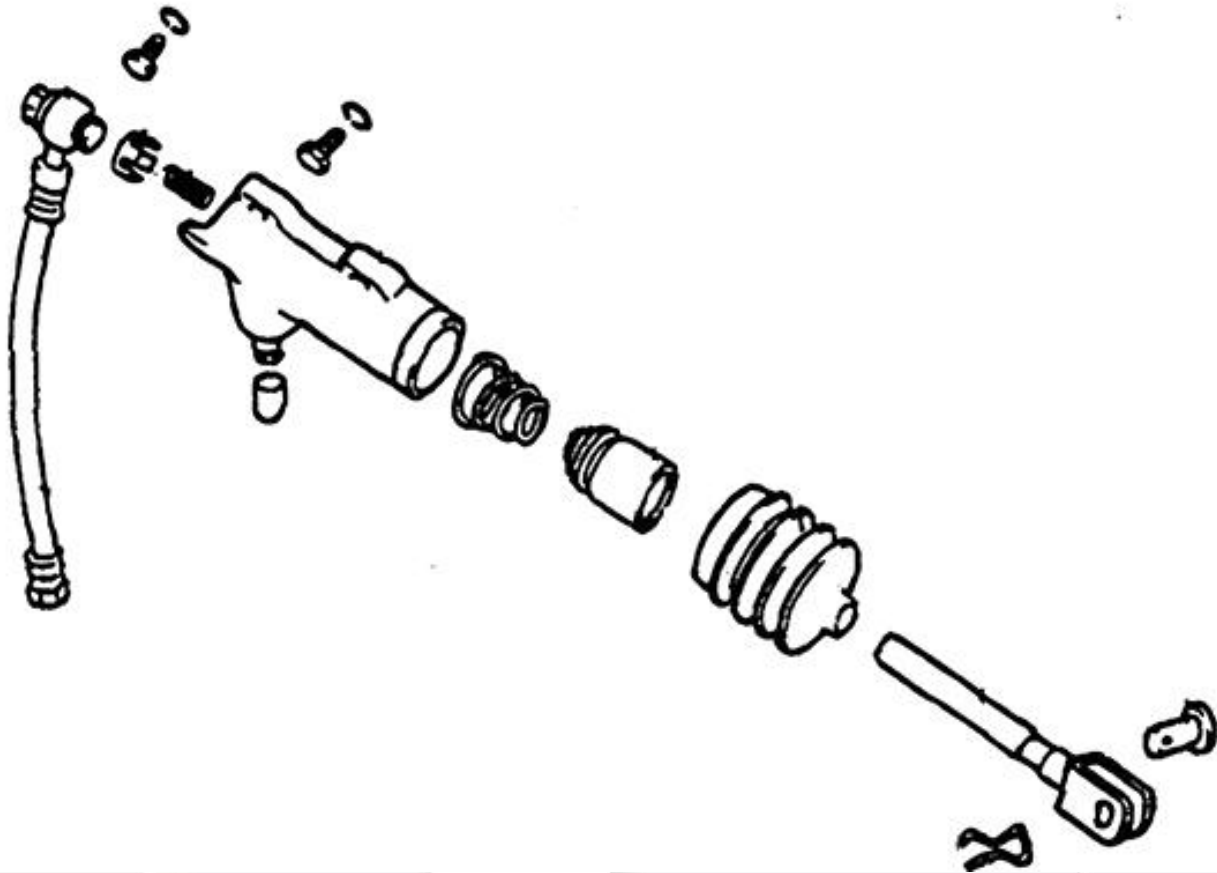

When the driver steps on the clutch pedal, the master cylinder is stressed. The pressure is passed to the Slave Cylinder through the pipeline, and Slave Cylinder uses this pressure to promote the separation mechanism to achieve the separation of the clutch. When the clutch pedal is released, the pressure is released and the clutch restores the joint.

Cluth Master Cylinder

The clutch Master Cylinder is mainly composed of push rod, piston, hydraulic pipeline, return spring and other components. Among them, the push rod is connected to the clutch pedal, and the piston is connected to the clutch Slave Cylinder through the hydraulic pipeline. When the driver steps on the clutch pedal, the push rod pushes the piston to move, increasing the oil pressure in the hydraulic pipeline, and then pushing the clutch Slave Cylinder to work and realize the separation of the clutch. When the driver releases the clutch pedal, the return spring pushes the piston and push rod back to their original position, and the clutch is re-engaged.

1. Pressure generation: The clutch Master Cylinder is usually located below the clutch pedal. When the driver steps on the clutch pedal, the push rod behind the pedal pushes the piston in the Master Cylinder.
2. Pressure transmission: The movement of the piston causes the liquid (or gas, depending on the system type) in the Master Cylinder to be compressed, generating pressure. This pressure is transmitted to the clutch Slave Cylinder through the oil pipe (or air pipe).
3. Application of Pascal's Law: The Master Cylinder clutch uses Pascal's Law, which states that when a liquid in a closed container is subjected to an external force, the pressure is instantly transmitted to all parts of the liquid. Therefore, the pressure generated by the Master Cylinder can be quickly transmitted to the Slave Cylinder.

Clutch Slave Cylinder

The clutch Slave Cylinder consists of the Slave Cylinder body and related parts (such as leather cups, springs, pistons, etc.). When the driver presses the clutch pedal, the piston of the clutch Master Cylinder moves. The pressure generated is transmitted to the clutch Slave Cylinder through the pipeline by the hydraulic oil. The Slave Cylinder receives the hydraulic oil transmitted from the Master Cylinder through the oil inlet. The pressure generated by the leather cup seal pushes the piston out and moves toward the clutch release bearing, thereby cutting off the power transmitted from the engine to the gearbox.

1. Receiving pressure: After the Slave Cylinder receives the pressure from the Master Cylinder, the piston or similar mechanism inside it will be pushed.
2. Operation of the release mechanism: The movement of the Slave Cylinder piston will drive the release fork (or similar mechanism), and the release fork will then push the release bearing forward to separate the clutch pressure plate from the clutch plate.
3. Return mechanism: When the driver releases the clutch pedal, the pressure in the Master Cylinder is released, and the piston in the Slave Cylinder returns to its initial position under the action of the return spring. The release fork and release bearing also return to their original positions, and the clutch pressure plate contacts the clutch plate again, thus achieving clutch engagement.

The brake pump is a vital component in the automobile braking system. Its basic function is to convert the force of the driver stepping on the brake pedal into hydraulic pressure (or air pressure) and transmit this pressure to other components of the braking system, such as the brake caliper or brake drum, so as to achieve the deceleration and stop of the vehicle. The brake pump plays a decisive role in the safety performance of the vehicle.

Classification

Hydraulic brake pump:

Principle: When the driver steps on the brake pedal, the piston in the brake Master Cylinder will be pushed, and the brake oil (brake fluid) will be transmitted to the piston of each brake Slave Cylinder through the oil pipe through the push rod, pushing the brake shoe or brake piston to open outward, so that the brake pad and the inner surface of the brake disc or brake drum will produce friction, thereby achieving the braking effect.

Structure: It mainly includes a tank for storing brake oil at the top and a cylinder with a piston at the bottom.

Application: It is widely used in various passenger cars and commercial vehicles.

Pneumatic brake pump (air brake pump):

Principle: Compressed air is generated by an air compressor, and then the air is transmitted to the brake pedal through a pipeline, pushing the brake pad and the brake disc to generate braking force.

Structure: It may include air booster, air reservoir, piston, push rod and other components.

Application: It is usually used in large commercial vehicles, trucks and public transportation vehicles, etc. where strong braking force is required.

Working Principle

Whether it is a hydraulic brake pump or an aerodynamic brake pump, its basic principle is to convert the driver's stepping force into a braking force through some way (hydraulic or air pressure), and pass it on to the wheel brake parts. In the hydraulic brake pump, this transformation is achieved through the flow of brake oil and the transmission of pressure; in the pneumatic brake pump, it is achieved by compressed the flow and pressure of the air.
